Abstract

Objectives: The paper presents a framework and tools for developing models useful for implementing complex Information Systems. It presents a case study for an Obstetrics-Gynecology Department and connected departments. The advantages of using models for creating complex OGD Information Systems together with a standardized communication will lead to an advanced interoperability and also will have benefits in patient care and in time will reduce the medical errors.

Methods: This paper presents the modeling process using the Generic Component Model (GCM) in four steps. The real OGD system is described based on the five RM-ODP (Reference Model of Open Distributed Processing) views. The paper presents the Obstetrics-Gynecology Department model based on the real workflow using Business Process Modeling and Notation and a specialized software - Bizagy. Communication between OGD and other medical units is based on HL7 Clinical Document Architecture CDA. The Obstetrics-Gynecology Department Information System (OGD IS) is developed based on the model, in Visual Studio.NET 2010, using ASP.NET pages and C# language, and Microsoft SQL Server 2008.

Results: The paper presents a model represented with Business Process Modeling and Notation and its possibilities to offer support for software developers to create flexible and portable information systems. Based on the workflow in the OGD, including the communication between OGD and other medical units, was developed a model and consequently the OGD IS.

Conclusions: For the future, the OGD IS will be extended with new functionalities: possibilities to introduce medication related to a Database in the cloud to receive suggested treatments. The advantages of using the OGD IS are reflected in a better patient care, and the treatments will be more documented which will determine less medical errors.

Model, Obstetrics-Gynecology Department Information System, HL7 CDA, GCM, model, Business Process Modeling and Notation, interoperability

1 Introduction

Interoperability between different medical information systems facilitates access to information and enhances the safety and quality of patient care despite its location. Information about patients is available much easier electronically and at the same time provides patients and medical professionals with updated and relevant information.

To meet the challenge for efficient, high quality, safe and sustainable care in developing countries, there is a need to extend and improve communication and cooperation between all actors participating in better patients’ care by creating interoperable health information systems.

Communication between different systems and their components in a complex and highly dynamic environment must fulfill several requirements: openness,
scalability, flexibility, portability; distribution at Internet level; standard conformance; business process orientation; consideration of timing aspects of data and information exchanged; user acceptance; lawfulness; appropriate security and privacy services.

An information system in obstetrics – gynecology department is very helpful in maintaining patient data. It is very helpful for medical staff to have information about the patient in real time. Because its specific characteristics, it can include medical data, ultrasound analysis, monitored information from pregnant’s lady home and other relevant information about the patient.

The paper presents the possibility to create complex healthcare information systems using models using as case study the current workflow in OGD modeled using Business Process Modeling and Notation. The communication between OGD and other medical units is ensured using HL7 CDA.

2 The Generic Component Model

The GCM is: “an architecture framework that enables the representation of any real or virtual system; includes the system architecture from its business prospective and the system’s development process for ICT solution supporting or enabling that business” [1] which was developed by professor Bernd Blobel from University Hospital Regensburg, Regensburg, Germany. The GCM is presented in Figure 1.

The Generic Component Model (GCM) provided the modeling framework for an obstetrics-gynecology department [5].

The steps reflecting the system development process based on the RM-ODP views are:

- defining the analyzed system, in this particular case the OGD IS,
- separation of the domain of current interest (here the medical one) from other domains which are not relevant for the moment (e.g., financial, administrative, security),
- composition/decomposition of the analyzed system, considering four granularity levels (business concepts, relations network, aggregations and details),

Figure 2: The real workflow in OGD.
model-driven development of the real OGD system based on the five RM-ODP views previously mentioned.

The OGD system is modeled using Business Process Modeling and Notation, and using Bizagy software. The paper [8] presents a previous version of the model of OGD workflow, and the current paper presents a new model which has more actions, including a monitoring component of the patient status. The OGD IS design and development process was presented in [6, 7]. For the future new functionalities will be available for the system. The model described in the following represents the Enterprise View.

3 Modeling the Obstetrics-Gynecology Department

Figure 2 presents the real workflow in the OGD using Business Process Modeling and Notation language usingBizagy Software [8].

The model connects several actors: Doctor, Nurse, Patient, Administrator, Patient monitoring system and External Hospital.

In Process 1 the main actor is the doctor. If he wants to introduce new data about a patient the first step is to authenticate and after the system verifies if the actor has access to introduce new data about a patient, proceeds. In the correct role he/she can input patient data (demographic, gynecology and obstetrics) into a Patient Record (this record is previously created) which has the data stored on a cloud or a server [8].

In Process 2 the main actor is the nurse that has access to the report for patient data and the monitoring report. She can add information about patient medication administration. Firstly, she has to authenticate herself and after the system checks that she has the appropriate rights, she can visualize the reports or input information about medication [8].

In Process 3 the main actor is the Patient monitoring system. The hospital can receive information about the patient monitored from home. If the patient monitoring system will send monitored information, the first step for the user is to authenticate himself/herself and after the system verifies if the actor has correct access rights, the data will be received and recorded in Patient Record.

In Process 4 the main actor is the administrator. If changes are needed into the system the first step is authentication and after the system verifies if the actor has access, the changes into the system are operated. If the actor has the correct role then he/she can express the will to delete an account or request a report about monitored information about the pregnancy [8].

In Process 6 the main actor is an external hospital which requests data about a patient. Firstly, it has to authenticate and the system checks the rights and if they are correct sends a request to OGD. If he has rights to access the information and if the information is available, the OGD IS will send an XML in HL7 CDA format or in the case if the information are not available than the external hospital will receive a message were will be written that the information about the patient requested are not available [8].

4 Obstetrics-Gynecology Department Information System

OGD IS is an application developed in Visual Studio.NET 2010, using ASP.NET and C♯ language. The database is using Microsoft SQL Server 2008. In the future the system will provide the possibility to receive data from systems which are for monitoring the patient from home (a mobile cardiotocography will give the possibility to send information about the pregnant woman to the doctor). There will be available a possibility to send patient medication to a database in a cloud connected to an application suggesting treatments based on previous doctors experience. The current doctor will have the possibility to choose that treatment or not.

Figure 4 presents an image from OGD IS where the doctor can add a consultation regarding gynecology data.

Figure 5 presents a screen shot from Obstetrics-Gynecology Department Information System where the doctor can add information about the examination.

It is important that the OGD IS has the possibility to communicate with other medical units, based on implemented interoperability between medical information systems. Figure 6 presents the communication framework between the OGD IS with other medical units.

To achieve interoperability we use XML files based on HL7 CDA standard. An example is in the case of OGD IS and Pediatrics Department communication. When the data of a new born child is added in the database of the
pediatrician, the physician will be asked if he/she wants to add the data manually or retrieve it from the database of the hospital, which technically is located in the server or private cloud of the Obstetrics and Gynecology unit, where the baby was born. When the data acquisition from the Obstetrics and Gynecology unit option is chosen, the Pediatrics application will create an XML file with the Personal Identification Number of the mother, date of birth of the child. The XML file with these data will be sent to the data server from the private cloud of the Obstetrics and Gynecology. When these dates are available in the server, via a specific application it will check the validity of the received message, will analyze the request and if the data exists in the server the application will form another XML file which contains the medical data record of the baby from birth until the day of discharge. These XML file is created in HL7 CDA standard format, and it will be sent to the unit who requested the data [9].

Once received, the required medical data in XML format, the Pediatrics application will read the XML file and will display the medical records to the location point where the physician adds the patient. The received medical data will be saved in the database server of the private cloud of the Pediatrics unit. The pediatrician will have access to the medical history of the baby from birth and during pregnancy, information important for monitoring and treating the child [9].

In Figure 5, the communication is realized using web server, but in the future will be uploaded in the cloud. The advantage of using the cloud solution is that information is always and anywhere available.

Applications communicate with each other better and more effectively using the HL7 CDA standard, due to its
features structuring the medical data on several levels and with certain codes that can be read by any application that uses these medical standards [9].

5 Conclusions

The paper presents the possibility to create complex healthcare information systems using models. It presents a case study for OGD IS modeled using Business Process Modeling and Notation with its processes. [8] presents a previous version of the model for the OGD workflow, and this paper presents a newer version which brings more actions related to the OGD. Based on the previous model the OGD IS basic system was developed, and in the future the new actions described by this paper model will be implemented. The communication between OGD IS and other medical units is using HL7 CDA with examples presented in the paper. A new component that will be added in the future is the possibility to use a specialized software tool that has as functionalities receiving treatments from different specialist from different locations and checking between given treatments, and suggesting a treatment. The doctor may or may not use the suggestion, having the possibility to approve it or not.

The paper [10] presents the steps and metrics for evaluating the interoperability of an Obstetrics-Gynecology Department Information System used in this paper and applied in Bega Clinic Timisoara regarding its readiness for interoperability in relation with similar systems. [10] presents also the amount of data related to the current system exchanged between the Obstetrics-Gynecology Department and other medical units. The obtained results were relatively good for the investigated data and structure of the system.

The work presented in this paper prepares a framework for flexible and quick development of OGD information systems supported by increased interoperability. Using the OGD IS medical staff will have a support for better patient care, the access to patient information will be in real time in the case of an emergency.

Using models before implementing an application improves the quality of the software, increases development speed, leads to a better maintainability and reusability, and also ensures better portability and interoperability.
